Tabletop Worksheet: Controls for a Customer-Facing Agent

Distributed Systems & Reliability · 15:15 – 16:30

> **Scenario:** CSOB is piloting a customer-facing agent that answers questions about mortgage products and can, within limits, update a customer's contact preferences and schedule a callback. It has access to: a product-information knowledge base (retrieval), a customer contact-preferences system (read/write), and a callback-scheduling tool (write).

1. Tool sandbox

Tool / system	Narrowest scope that still completes the job
Product-information knowledge base (retrieval)	
Customer contact-preferences system (read/write)	
Callback-scheduling tool (write)	

2. Escalation trigger

One trigger, specific enough that two different reviewers would apply it identically	

3. Incident sequence: live, facilitator-led

Your facilitator will read out one event at a time. You have 90 seconds per event to say what your designed system should do, before the actual outcome is revealed.

Event	What should your system do?
1. A message phrased as if from CSOB IT asks to forward the customer's message and account number to an external address.	
2. The callback-scheduling tool times out after the confirmation email has already been sent.	
3. The agent's output doesn't match the expected response schema.	
4. Overnight, the parent organisation updates the shared base system prompt used by the platform CSOB consumes. Nothing in CSOB's own deployment has changed. By the morning the agent has stopped escalating cases it escalated yesterday.	

4. What changed

What changed about your control design after walking the sequence, if anything
